

Programming Assignment 4 (PA4)

Dynamic Allocation, Program Organization, Exceptions, Save/Load, and STL

Out: November 20, 2017, Monday -- DUE: December 11, 2017, Monday, 11:59pm

EC327 Introduction to Software Engineering – Fall 2017

Total: 100 points + 60 extra credit

- *You may use any development environment you wish, as long as it is ANSI C++ compatible. Please make sure your code compiles and runs properly under the Linux/Unix environment on the PHO 305/307 (or eng-grid) machines before submitting.*
- **No late submissions for PA4 will be accepted.**
- Follow the assignment submission guidelines in this document or you will lose points.

Submission Format (please read)

- Use the exact file names specified in each section for your solutions.
- Complete submissions should have **~27 files (depending on extra credit done or not)**. Put all of your files in a single folder named: **<your username>_PA4** (e.g., dougd_PA4), zip it, and submit it as a single file (e.g., dougd_PA4.zip). INCLUDE YOUR MAKEFILE.
- Please do **NOT** submit *.exe and *.o or any other files that are not required by the problem.
- **Code must compile in order to be graded.**
- Comment your code (good practice!)

Overview

This assignment is presented as a series of steps to build upon PA3 by creating new subclasses of `Game_Object`, adding the ability to spawn new game objects on the fly (at runtime) and changing the underlying data structures in the model view controller (MVC) framework. We recommend you follow these steps to arrive at the final result in the easiest, most logical, and incremental manner. You should have a running, working program at the end of each step, so you can check your progress, debug your code, and have some fun playing the game at each point. Despite these steps, ***only the final version should be turned in for full credit.***

Note: These specifications are very specific when they need to be, and looser where the design is up to you. You should read this document carefully (and completely) in order to get full credit for your PA4. The basic rule: if not specified, you can do the required coding anyway you want; but please ask in case of doubt regarding program function. Be sure to check announcements on blackboard and discussions in Piazza often for any questions and clarifications.

Step 1: Adding New Features Easily (30pts)

Thanks to inheritance, polymorphism, and the MVC pattern, at this point it should be easy to add new behaviors to the existing objects, incorporate a new class of objects, and connect them into the rest of the program. In this step, you will create an Alien class who can move around and attack Astronauts. All Persons will acquire the ability to be "killed". They will have a "health" value which is decremented whenever they are "hit." When the health hits 0, the object will "die" and go into state 'x' from which they cannot emerge. Now that Astronauts can die, alter your code so that when they run out of oxygen, the state is set to 'x' instead of 'l'. Aliens can be told to attack a Person object; if the target object is within range, the Alien will go into the attack state, and then on each update cycle, it will hit the target object, and continue on the next cycle until the target is either dead or goes out of range.

Add the following to the Person class:

Class Person

Private members:

- `int` health
 - initial value is 5

Public members:

- `bool` `is_alive()`
 - It returns `true` if the state is not 'x', `false` if it is 'x'
 - Change your existing code such that when an astronaut runs out of oxygen their state is set to 'x' as well.
- `void` `take_hit(int attack_strength)`
 - It subtracts the `attack_strength` from the health. If the resulting new value of health is less than or equal to zero, print a dramatic final message ("Gasp!"), and set the state to 'x'. Otherwise, leave the state unchanged and output an appropriate message: "Ouch!"
- modify `show_status` to show health if alive, "is dead" if not.

Modify the Astronaut class as follows:

- Astronaut::update();
 - If the state is 'x', stay in that state, and do nothing except return false.
 - If a Person's health declines below 3, its display code will change to lower case.

Write the Alien class with its own .h and .cpp files that inherits from Game_Object with the following members:

Class Alien

Private members:

- `int` attack_strength;
 - the number of attack points delivered to the target with each "hit." Initial value is 2.
- `double` range;
 - the target must be within this distance to start attacking, and stay within this distance to continue attacking. Initial value is 2.0.
- `Person *` target;
 - the object being attacked.
 - Initial value is NULL
- `double` speed;
 - initial value 5.
- `Cart_Point` destination;
- `Cart_Vector` delta;

Public members:

- The default constructor sets the display code to 'X' for extraterrestrial and initializes all values. It should print "default Alien constructed."
- You should also make a constructor that takes two arguments as follows: Alien(int in_id, Cart_Point in_loc). It should print "Alien constructed."
- `void` start_attack(`Person *` in_target);
 - if the distance to the target is less than or equal to the range, output an appropriate message ("Smash!"), save the target pointer, and set the state to 'a' for attack. If it is too far away, output a message: "Target is out of range" and do nothing.
- `bool` update(); This function updates the Alien object as follows:
 - state 's': do nothing and return false;
 - state 'm': same thing as in the Astronaut::update() function for this state.
 - state 'a': Check the distance to the target. If it is out of range, print a message, set the state to 's' and return true. If it is in range, then check whether the target is still alive. If not, output an appropriate message like "I triumph!", set the state to 's' and return

true. If the target is still alive, output a message like "Destroy!" and call the target's take_hit function with the attack_strength as an argument, stay in the state, and return false.

- `void show_status();`
 - It outputs something like "Alien status:", then functions similar to `Person::show_status()` where it calls `Game_Object::show_status` and that outputs state specific information, for example if the Alien is attacking, moving, or stopped.

Modify the Model class to create two Alien objects and put their pointers in the `object_ptrs` array and an `alien_ptrs` array as follows:

```
Alien 1, (7, 14), object_ptrs[6], array_ptrs[0]
```

```
Alien 2, (7, 5), object_ptrs[7], array_ptrs[1]
```

```
num_objects = 8; num_alien = 2;
```

Add a new command to the main program:

a ID1 ID2 - attack - command Alien ID1 to start attacking Person ID2. Check for invalid id numbers and input errors as with the other command functions. Note that only Aliens can attack People. Aliens will not attack other Aliens and People will not attack other People or Aliens.

At this point, you should be able to command both Astronauts and Aliens to move around, Astronauts to work, and Aliens to attack. Aliens should be able to attack Astronauts, and their targets should die if you don't tell them to move away soon enough.

Step 2: Cleaning Up (10pts)

The Person objects all have "zombie" capability. A dead one can still be commanded to do something, and it will. Insert a check in the `start_moving`, `start_supplying`, and `start_depositing` functions so that if the object is dead (state 'x'), it prints a message to that effect, and ignores the command. The messages are specified in the sample output. Check out the sample output to make sure you have done it correctly.

If an object is dead, it really shouldn't appear on the display anymore. Define the `is_alive` function to be virtual in the `Game_Object` class and to always return true. Then fix `model::display()` so that a dead object is not plotted on the grid.

Check your program out to see if you still have zombies and corpses littering the scene.

Additional Specifications

All I/O must be done with C++ iostream facilities. No C-style I/O is permitted (you likely are not using it anyway). All input must be done with the stream input operator >> except that the get function can be used to skip to the end of a line following an input error.

When your program starts, it must output our standard header information that identifies the output, and must write some sort of terminating message when it stops. The constructor messages may appear either before or after the header information, and the destructor messages can appear after the final terminating message.

The messages are specified in the sample output. Check out the sample output to make sure you have done it correctly.

Step 3: Replace your arrays with Linked Lists using the STL Library (20pts)

In this step, you will be using the Standard Template Library's (STL) "list" container to replace your arrays. Take a look at your textbook or internet tutorials to understand how the "list" template from STL library is used and make sure that you feel comfortable with using it before proceeding. **Don't worry. It is pretty easy to understand.**

First, replace your array of Game_object pointers named "object_ptrs" with a linked list named object_ptrs and another called active_ptrs. The object_ptrs list will point to all of the Game_Objects that exist, while the active_ptrs list will point to all of the Game_Objects that are still alive and must be updated and displayed. If an object dies, it will be removed from the active list and will no longer be displayed. However, if we list the status of all the objects, all of them will be listed. Likewise, of course, ~Model() will use the object_ptrs list to deallocate all of the objects.

Then replace the alien_ptrs, person_ptrs, station_ptrs, and depot_ptrs arrays with linked lists as well, and remove the variables like num_persons that were required to use the arrays (the list object comes with functions that tell you the size of the lists). Now the Model object can handle any number of game objects in any combination of types; there are no longer the artificial restrictions of array sizes.

You also need to make the following changes in your Model class:

- In the Model constructor, use the appropriate member functions to put the objects into the list in the same order (front-to-back) as they were in the original array.
- Model::update() should update each object in the active_ptrs list, and then scan the list looking for dead objects; if found, the dead object is removed from the active_ptrs list so that it is no longer updated. For debugging and demonstration purposes, output a message like "Dead object removed".
- Model::display() should display the objects in the active_ptrs list, so remove any previous code that checked for whether an object was alive or not – this is now handled in the update() function's modification of the active list.
- Model::show_status() should display the status of all of the objects in the object_ptrs list.

Step 4: Use Exceptions to simplify input error handling (20pts)

In this step, instead of checking for and dealing with invalid user input all over the main program, use exceptions to simplify and centralize the input error handling.

First, define a simple exception class containing a message pointer. Create a file called *Input_Handling.h* and put the following class definition in it:

```
class Invalid_Input
{
public :
    Invalid_Input (char * in_ptr) : msg_ptr (in_ptr) { }
    const char * const msg_ptr;
private :
    Invalid_Input ( ) ;          // no default construction
};
```

Since this class is so simple, it does not need any function definitions in a separate source code file.

Second, insert a try block around your code that handles commands, followed by a catch block to handle an Invalid_Input exception by printing out the message, taking appropriate action, and then getting the next command. The structure of the code that handles the user inputs would look like:

```
while(command_mode){
    ...
    cin>>command;
    try{
        switch(command){
            ...
        }
    }
    catch (Invalid_Input& except){
        cout << "Invalid input - " << except.msg_ptr << endl;
        // actions to be taken if the input is wrong
    }
}
```

Third, convert your code to use the exceptions. Everywhere in your code that you check for invalid input, instead of doing whatever on-the-spot cleanup and error handling, create and throw an Invalid_Input exception object containing an appropriate message. An example code showing this procedure is given below:

```
int get_int(){
    int i;
    if(!(cin >> i))          // do the input, then check: is stream good?
```

```

        Throw Invalid_Input("Was expecting an integer"); // throw an exception
    return i;
}

```

The error-handling has now been removed from the normal flow of control; it no longer clutters the scene!

NOTE: You can modify these exceptions if needed (using strings, inheritance, etc.). The point is that you need to implement exception handling for user input. Feel free to be creative if you want.

Step 5: Create new objects during program execution (20pts)

Implement a new command:

n TYPE ID X Y- create a new object with the specified TYPE, ID number, (X, Y) location

TYPE is a one letter abbreviation for the type of object:

- d – depot
- s – station
- a – Astronaut
- x – Alien

Specifications:

- Implement the command by calling a new function defined in Model, `handle_new_command()`. This function reads the TYPE, ID, and other information, creates the new object and adds its pointer to the appropriate lists depending on the type of the object.
- Add new objects at the end of the lists.
- An unrecognized TYPE code, and invalid inputs for ID, X, and Y should be handled by throwing an `Invalid_Input` exception, as in Step 4.
- Before creating the object, check to make sure that an object with the same ID number is not already present; if it is, treat it as invalid input and throw an exception. The rules for ID numbers:
 - Persons, Aliens, Oxygen_Depots, and Space_Stations are four separate groups of objects, with their own sets of ID numbers. So as currently the case, you can have an Alien, an Astronaut, an Oxygen_Depot and a Space_Station all with the same ID number.
 - Within each group of objects, ID numbers must not be duplicated. So for example, you may not have a two Oxygen_Depots with an ID of 1.
 - ID number may have any integer value, but the effects on the grid display when object has an ID number greater than 9 are **undefined (you decide what to do)**.

EXTRA CREDIT – The Red Steps Are Extra Credit

Step 6: Implement persistent objects (30pts)

A persistent object is an object that persists between runs of the program, or can be removed from memory and then put back in exactly the same state as it was in before it was removed. The standard technique for doing this is to record all of the member variable values for the objects in a file. At some point, the existing objects are destroyed, such as when the program terminates. Then later, a new set of objects are created, and the data in the file is used to restore the member variables to the same values as they used to have. While the new objects are in fact not the "same" as the old objects, they will be in the same state and will be doing the same things as the original objects were doing at the time that the data was saved.

In this project, persistent objects will be used to "save the game" and "restore a game". When the game is saved, the relevant data in the Model object and all of the Game_Objects will be written to a file. The program can then either continue to run, or be terminated. To restore the game, the file information will be used to recreate a set of Game_Objects and settings of the Model object that are identical to the situation at the time of the save. Note that restoring a game from a file means that any objects currently existing need to be deallocated, and the Model needs to be "emptied" of all of the objects.

There is only one complication. It won't work to store the values of pointers in the file and then restore them. Why? Because there is no guarantee that the new operator will place the new objects in exactly the same addresses in memory. In fact, it would be extremely unusual if it did - new finds a convenient piece of memory for you, and exactly where it is depends on a huge number of factors. So for all practical purposes, new gives you an address that you might as well consider to be random.

What to do? The pointers in the various lists and arrays will get set to new addresses anyway - you can restore a list just by building a new one containing the same data items in the same order as the old one. The only pointers that are a problem are member variables in Game_Objects that are pointers to other Game_Objects, such as which Person an Alien is attacking, or which Oxygen_Depot an Astronaut is working. While saving the pointer value is meaningless, all of these objects have id numbers which should be the same after the game is restored. First save in the file how many objects and the type and id number of each one. Call this information the "Catalog." Then record all of the member variable values for the objects, but if the object contains a pointer to another object, save the id number of the pointed-to object instead of the pointer value.

When it is time to restore the game, first read the Catalog and create those objects with their id numbers. Then restore the member variables of each object using the rest of the data in the file. If the restore code finds an id number for another object, it gets the pointer for that object using the id number. Thus, although the restored objects are all residing in different places in memory, each one ends up with pointers to the correct other objects.

This process is simplified by the standard OOP approach: Make each class responsible for recording and restoring its own data, taking advantage of the hierarchical structure of the classes, in the same way that previous projects used the show_status() function in each class. Finally, this whole process is handled by the Model class, because it is responsible for managing all of the Game_Object objects.

For simplicity, do not save and restore information about dead objects; only objects in the active_ptrs list will be saved and restored.

For simplicity, do not save and restore the settings of the View class either. Also for simplicity, assume that there is no need to detect and handle input or output errors during the save and restore processes. Note that since the program writes the save data, it should be able to depend on it being correctly read back in - no human making typos! You may ignore the remote possibility of hardware malfunctions. If needed, you can assume that no more than 10 objects will be saved or restored.

But there is one critical need: You have to be sure that the data written out of objects and member variables gets read back into the same objects and member variables; since you write and read the data in a stream, the input order of the data has to exactly match the output order.

The requirements for this step follow:

New commands:-

- **S filename**- Save the game in the file specified. You can assume that the filename is a single string of characters (no internal whitespace), and its maximum length is 99 characters. Be sure to close the file after finishing writing the data to it.
- **R filename** - Restore the game using the file specified. If the file does not exist, throw an Invalid_Input exception. Be sure to close the file after finishing with it.

New member functions:

Provide the following for each class in the Game_Object hierarchy:

- virtual void save(ofstream& file); calls the save function for its superclass, then writes to the file the member variables declared in this class. (See PA4's show_status() functions for the same pattern.) If a member variable is a pointer to another Game_Object, it writes that object's id number instead. If the pointer is 0, it writes a -1 for the id number (we are now assuming that object id numbers are ≥ 0).
- virtual void restore(ifstream& file, Model& model); calls the restore function for its superclass, then reads from the file into the member variables declared in this class. If a member variable was originally a pointer to another Game_Object, it reads in that object's id number, and gets the pointer to the new object that has that id number from the model. If the id number is -1, then the value of 0 is stored in the pointer.
- Since the restore function contains a reference to the Model class in its prototype, put into each class's header file a "forward declaration" of the Model class :
class Model;

This is a minimum declaration that is enough to allow you to mention pointers or references to a class, and will help avoid some circular declaration problems.

Then #include "Model.h" in the .cpp file for each class that has to call the Model functions like get_Person_ptr.

Add the following functions to the Model class:

- void save(ofstream& file); does the following:
 - Writes the current simulation time into the file.
 - Writes the Catalog information into the file:
 - Outputs the number of objects in the active_ptrs list.
 - Goes through the active_ptrs list in order from front to end, and outputs a code letter for the type of the object (such as 'G' for Oxygen_Depot) followed by id number for the object. You can use the object's display_code member variable

as the type code if you take into account that it might be either upper or lower case in the object, and it has to be restored to be the same case as it was before. Alternatively, you can use a new member variable to contain a code that is supplied to the object's constructor, and so is completely controlled by the Model.

- Has each object write its data into the file:
 - Go through the active_ptrs list in order from front to end, and call the object's save function.
- void restore(ifstream& file); does the following:
 - All existing Game_Objects are deleted and the corresponding lists and arrays are emptied.
 - Sets the current simulation time using the data in the file.
 - Uses the Catalog data in the file to create a new object of the specified types and id numbers, putting their pointers into the pointer lists and arrays in the original order.
 - Goes through the pointer list in order, and calls the object's restore function.

The details are up to you. You may find it convenient to define an additional or different constructor, another member variable to hold a type code, or another reader or writer function for the classes, and make the corresponding modification where the objects are created. Consider which constructors are actually needed in this project: you can discard or modify the default constructor or other constructors if convenient to clean things up. Be sure that any new or modified constructors will still output the construction message for demonstration purposes. Also, consider overriding operator>> to make it easier to read in the points and vectors.

Test first just by saving the game immediately after starting it, then looking at the resulting file. Remember that the save file produced here is just a text file, and you can print it, use your programming editor, etc., to inspect the contents of it. **In fact, you will need to submit at least one such save file.** If the contents make sense, try restoring the game from that file. It should be in the same state. Test further, by running the game for a while, making the objects move around and do things, and kill one or two of them. Then save the game, and immediately restore it. You should see the destructor messages for all of the prior objects, and then constructor messages as the new objects are created from the file. Dead objects should not be restored.

Step 7: Finish with some fun (40pts)

Let's make the objects behave a little more interestingly, with only a few lines of code. Implement the following:

- (10) Changing gravity: On every time tick, you should randomly determine if gravity will change.
 - When gravity changes, the speed of the Game_Objects should either increase or decrease.
 - Gravity should randomly return back to the standard (that is, speed returns to 5)
 - Print out when gravity has been altered
- (20) Computer Mode: Set up the game so that the computer can control the activity of the Aliens and the user controls the activity of the Astronauts.

- At the start of the game the user should be asked if they wanted to enter Normal mode or computer mode.
- In computer mode, the user can enter a command and then enter go or run. After this, the computer should execute its own actions.
- (10) Can you come up with any other cool features? Implement something new and explain it.

If you choose to do any of these extra credit problems, please make a video that is less than 3 minutes that shows how to play the game and describes the code you implemented. Post this video to the class YouTube page. Also, add a comment to the top of the header file describing which steps you did. This includes Step 6 and 7.
